Not in general a mass eigenstate. See note on neutrino properties above.

Written April 1996 by D.E. Groom (LBNL).
These limits apply to $\nu_{1}$, the primary mass eigenstate in $\nu_{e}$. They would also apply to any other $\nu_{j}$ which mixes strongly in $\nu_{e}$ and has sufficiently small mass that it can occur in the respective decay. The neutrino mass may be of a Dirac or Majorana type; the former conserves total lepton number while the latter violates it. Either would violate lepton family number, since nothing forces the neutrino mass eigenstates to coincide with the neutrino interaction eigenstates. For limits on a Majorana $\nu_{e}$ mass, see the section on "Searches for Massive Neutrinos and Lepton Mixing," part (C), entitled "Searches for Neutrinoless Double- $\beta$ Decay."

The square of the neutrino mass $m_{\nu_{e}}^{2}$ is measured in tritium beta decay experiments by fitting the shape of the beta spectrum near the endpoint; results are given in one of the tables in this section. In many experiments, it has been found to be significantly negative. In the 1994 edition of this Review, it was noted that the combined probability of a positive result was $3.5 \%$. The problem has been exacerbated by the precise and careful experiments reported in two new papers (BELESEV 95 and STOEFFL 95). Both groups conclude that unknown effects cause the accumulation of events in the electron spectrum near its end point. If the fitting hypothesis does not account for this, unphysical values for $m_{\nu_{e}}^{2}$ are obtained. BELESEV 95 obtain their value for $m_{\nu_{e}}^{2}$ and limit for $m_{\nu_{e}}(4.35 \mathrm{eV}$ at $95 \% \mathrm{CL})$ under the assumption that a certain narrow region is free of both high-energy and low-energy anomalies. Including the endpoint accumulation (they find no low-energy anomaly), STOEFFL 95
find a value for $m_{\nu_{e}}^{2}$ which is more than 5 standard deviations negative, and report a Bayesian limit of 7 eV for $m_{\nu_{e}}$ which is obtained by setting $m_{\nu_{e}}^{2}=0$. Given the status of the tritium results, we find no clear way to set a meaningful limit on $m_{\nu_{e}}$. On the other hand, a mass as large as $10-15 \mathrm{eV}$ would probably cause detectable spectrum distortions near the endpoint.

The spread of arrival times of the neutrinos from SN 1987A, coupled with the measured neutrino energies, should provide a simple time-of-flight limit on $m_{\nu_{e}}$. This statement, clothed in various degrees of sophistication, has been the basis for a very large number of papers. The LOREDO 89 limit ( 23 eV ) is among the most conservative and involves few assumptions; as such, it is probably a safe limit. We list this limit below as "used," but conclude that a limit about half this size is justified by the tritium decay experiments.

## $\nu_{e}$ MASS

Most of the data from which these limits are derived are from $\beta^{-}$decay experiments in which a $\bar{\nu}_{e}$ is produced, so that they really apply to $m_{\bar{\nu}_{1}}$. Assuming CPT invariance, a limit on $m_{\bar{\nu}_{1}}$ is the same as a limit on $m_{\nu_{1}}$. Results from studies of electron capture transitions, given below " $m_{\nu_{1}}-$ $m_{\bar{\nu}_{1}}$ ", give limits on $m_{\nu_{1}}$ itself. OUR EVALUATION of the present status of the tritium decay experiments is discussed in the above minireview.

${ }^{1}$ BELESEV 95 (Moscow) use an integral electrostatic spectrometer with adiabatic magnetic collimation and a gaseous tritium sources. A fit to a normal Kurie plot above 18300-18350 eV (to avoid a low-energy anomaly) plus a monochromatic line $7-15 \mathrm{eV}$ below the endpoint yields $m_{\nu}^{2}=-4.1 \pm 10.9 \mathrm{eV}^{2}$, leading to this Bayesian limit.
${ }^{2}$ CHING 95 quotes results previously given by SUN 93 ; no experimental details are given. A possible explanation for consistently negative values of $m_{\nu}^{2}$ is given.
${ }^{3}$ HIDDEMANN 95 (Munich) experiment uses atomic tritium embedded in a metal-dioxide lattice. Bayesian limit calculated from the weighted mean $m_{\nu}^{2}=221 \pm 4244 \mathrm{eV}^{2}$ from the two runs listed below.
${ }^{4}$ STOEFFL 95 (LLNL) result is the Bayesian limit obtained from the $m_{\nu}^{2}$ errors given below but with $m_{\nu}^{2}$ set equal to 0 . The anomalous endpoint accumulation leads to a value of $m_{\nu}^{2}$ which is negative by more than 5 standard deviations.
${ }^{5}$ The YASUMI 94 (KEK) limit results from their measurement $m_{\nu}=110_{-110}^{+350} \mathrm{eV}$.
${ }^{6}$ WEINHEIMER 93 (Mainz) is a measurement of the endpoint of the tritium $\beta$ spectrum using an electrostatic spectrometer with a magnetic guiding field. The source is molecular tritium frozen onto an aluminum substrate.
${ }^{7}$ HOLZSCHUH 92B (Zurich) result is obtained from the measurement $m_{\nu}^{2}=-24 \pm 48 \pm 61$ ( $1 \sigma$ errors), in $\mathrm{eV}^{2}$, using the PDG prescription for conversion to a limit in $m_{\nu}$.
${ }^{8}$ KAWAKAMI 91 (Tokyo) experiment uses tritium-labeled arachidic acid. This result is the Bayesian limit obtained from the $m_{\nu}^{2}$ limit with the errors combined in quadrature. This was also done in ROBERTSON 91, although the authors report a different procedure.
${ }^{9}$ ROBERTSON 91 (LANL) experiment uses gaseous molecular tritium. The result is in strong disagreement with the earlier claims by the ITEP group [LUBIMOV 80, BORIS 87 (+ BORIS 88 erratum)] that $m_{\nu}$ lies between 17 and 40 eV . However, the probability of a positive $\mathrm{m}^{2}$ is only $3 \%$ if statistical and systematic error are combined in quadrature.
${ }^{10}$ See also comment in BORIS 87B and erratum in BORIS 88.

## $\nu_{e}$ MASS SQUARED

The tritium experiments actually measure mass squared. A combined limit on mass must therefore be obtained from the weighted average of the results shown here. The recent results are in strong disagreement with the earlier claims by the ITEP group [LUBIMOV 80, BORIS 87 (+ BORIS 88, erratum)] that $m_{\nu_{1}}$ lies between 17 and 40 eV . The BORIS 87 result is excluded because of the controversy over the possibly large unreported systematic errors; see BERGKVIST 85B, BERGKVIST 86, SIMPSON 84, and REDONDO 89. However, the average for the new experiments given below
implies only a $3.5 \%$ probability that $m^{2}$ is positive．See HOLZSCHUH 92 for a review of the recent direct $m_{\nu_{1}}$ measurements．

${ }^{26}$ RAFFELT 85 limit is from solar $x$ - and $\gamma$-ray fluxes. Limit depends on $\nu$ flux from $p p$, now established from GALLEX and SAGE to be $>0.5$ of expectation.
${ }^{27}$ REINES 74 looked for $\nu_{e}$ of nonzero mass decaying to a neutral of lesser mass $+\gamma$. Used liquid scintillator detector near fission reactor. Finds lab lifetime $6 . \times 10^{7} \mathrm{~s}$ or more. Above value of (mean life)/mass assumes average effective neutrino energy of 0.2 MeV . To obtain the limit $6 . \times 10^{7}$ s REINES 74 assumed that the full $\bar{\nu}_{e}$ reactor flux could be responsible for yielding decays with photon energies in the interval $0.1 \mathrm{MeV}-0.5$ MeV . This represents some overestimate so their lower limit is an over-estimate of the lab lifetime (VOGEL 84). If so, OBERAUER 87 may be comparable or better.
28 BLUDMAN 92 sets additional limits by this method for higher mass ranges. Cosmological limits are also obtained.
${ }^{29}$ Nonobservation of $\gamma$ 's in coincidence with $\nu$ 's from SN 1987A.
30 KRAKAUER 91 quotes the limit $\tau / m_{\nu_{1}}>\left(0.3 a^{2}+9.8 a+15.9\right) \mathrm{s} / \mathrm{eV}$, where $a$ is a parameter describing the asymmetry in the neutrino decay defined as $d N_{\gamma} / d \cos \theta=$ $(1 / 2)(1+a \cos \theta) \quad a=0$ for a Majorana neutrino, but can vary from -1 to 1 for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for $a=-1$ ).
31 CHUPP 89 should be multiplied by a branching ratio (about 1 ) and a detection efficiency (about $1 / 4$ ), and pertains to radiative decay of any neutrino to a lighter or sterile neutrino.
${ }^{32}$ Model-dependent theoretical analysis of SN 1987A neutrinos.
33 OBERAUER 87 bounds are from comparison of observed and expected rate of reactor neutrinos.
${ }^{34}$ STECKER 80 limit based on UV background; result given is $\tau>4 \times 10^{22}$ s at $m_{\nu}=20$ eV.

## $|(v-c) / c|\left(v \equiv \nu_{1}\right.$ VELOCITY $)$

Expected to be zero for massless neutrino, but tests also whether photons and neutrinos have the same limiting velocity in vacuum.

35 STODOLSKY 88 result based on $<10 \mathrm{hr}$ between $\bar{\nu}_{e}$ detection in IMB and KAMI detectors and beginning of light signal. Inclusion of the problematic 5 neutrino events from FREJ (four hours later) does not change the result.
36 LONGO 87 argues that uncertainty between light and neutrino transit times is $\pm 3 \mathrm{hr}$, ignoring FREJUS events.

## $\nu_{1}$ MAGNETIC MOMENT

Must vanish for Majorana neutrino or purely chiral massless Dirac neutrino. The value of the magnetic moment for the standard $S U(2) \times U(1)$ electroweak theory extended to include massive neutrinos (see FUJIKAWA 80) is $\mu_{\nu}=3 e G_{F} m_{\nu} /\left(8 \pi^{2} \sqrt{2}\right)=\left(3.20 \times 10^{-19}\right) m_{\nu} \mu_{B}$ where $m_{\nu}$ is in eV and $\mu_{B}=e \hbar / 2 m_{e}$ is the Bohr magneton. Given the upper bound $m_{\nu_{1}}$ $<7.3 \mathrm{eV}$, it follows that for the extended standard electroweak theory, $\mu\left(\nu_{1}\right)<2.3 \times 10^{-18} \mu_{B}$. Current experiments are not yet challenging this limit. There is considerable controversy over the validity of many of the claimed upper limits on the magnetic moment from the astrophysical data. For example, VOLOSHIN 90 states that "in connection with the astrophysical limits on $\mu_{\nu}, \ldots$ there is by now a general consensus that contrary to the initial claims (BARBIERI 88, LATTIMER 88, GOLDMAN 88, NOTZOLD 88), essentially no better than quoted limits (from previous constraints) can be derived from detection of the neutrino flux from the supernova SN1987A." See VOLOSHIN 88 and VOLOSHIN 88C.

37 DERBIN 94 supersedes DERBIN 93.
38 ELMFORS 97 calculate the rate of depolarization in a plasma for neutrinos with a magnetic moment and use the constraints from a big-bang nucleosynthesis on additional degrees of freedom.
39 GOVAERTS 96 limit is on $\sqrt{\Sigma \mu \nu_{\ell}^{2}}$, based on limits on $2 \nu$ decay of ortho-positronium.
40 GOYAL 95 assume that helicity flip via $\mu_{\nu}$, would result in faster cooling and hence shorter burst from SN1987A. Limit is based on the assumed presence of a pion condensate or quark core in the remanant.
41 VIDYAKIN 92 limit is from a $e \bar{\nu}_{e}$ elastic scattering experiment. No experimental details are given except for the cross section from which this limit is derived. Signal/noise was $1 / 10$. The limit uses $\sin ^{2} \theta_{W}=0.23$ as input.
42 KRAKAUER 90 experiment fully reported in ALLEN 93.
43 RAFFELT 90 limit applies for a diagonal magnetic moment of a Dirac neutrino, or for a transition magnetic moment of a Majorana neutrino. In the latter case, the same analysis gives $<1.4 \times 10^{-12}$. Limit at $95 \%$ CL obtained from $\delta M_{C}$.
44 Significant dependence on details of stellar models.
${ }^{45}$ A limit of $10^{-13}$ is obtained with even more model-dependence.
46 These papers have assumed that the right-handed neutrino is inert; see BARBIERI 88B.
47 FUKUGITA 88 find magnetic dipole moments of any two neutrino species are bounded by $\mu<10^{-16}\left[10^{-9} G / B_{0}\right]$ where $B_{0}$ is the present-day intergalactic field strength.
48 Some dependence on details of stellar models.
49 We obtain above limit from SUTHERLAND 76 using their limit $f<1 / 3$.

## NONSTANDARD CONTRIBUTIONS TO NEUTRINO SCATTERING

We report limits on the so-called neutrino charge radius squared in this section. This quantity is not an observable, physical quantity and this is reflected in the fact that it is gauge dependent (see LEE 77C). It is not necessarily positive. A more general interpretation of the experimental results is that they are limits on certain nonstandard contributions to neutrino scattering.

50 VIDYAKIN 92 limit is from a $e \bar{\nu}_{e}$ elastic scattering experiment. No experimental details are given except for the cross section from which this limit is derived. Signal/noise was $1 / 10$. The limit uses $\sin ^{2} \theta_{W}=0.23$ as input.
51 GRIFOLS 89B sets a limit of $\left\langle r^{2}\right\rangle<0.2 \times 10^{-32} \mathrm{~cm}^{2}$ for right-handed neutrinos.
